Three efforts are currently underway in which New York Sea Grant (NYSG) has been successful in bringing significant external financial resources to bear on critical and newly-developing environmental issues. “While each is in a different stage of implementation,” explains NYSG Assistant Director Cornelia Schlenk, “the stories of their evolution serve to illustrate the groundwork, methods, and networks our program utilizes to make these new initiatives a reality.” Brown tide efforts are now in their fifth year of special funding (see pages 6-7 for the latest findings), research selected under a hard clam initiative is in its first field season, and a lobster mortality/shell disease program has just started. “We have established an effective method in our approach and management of such initiatives that is becoming well-recognized as a successful model,” says Schlenk. “These initiatives demonstrate that NYSG responds to emerging questions and stimulates others to do so as well.”

**Shoring Up Support for Hard Clams**

Hard clams— including such market sellers as chowders, cherrystones, and littlenecks (the smallest and most valuable of the bunch)—had been economic and ecological cornerstone of Long Island’s South Shore Estuary area. Some 30 years ago, New York, with its Great South Bay considered “the world’s richest clam factory,” provided more than 60 percent of the nation’s hard clams.

In 1976, landings of hard clams (Mercenaria mercenaria) hit an all-time record, totaling more than 700,000 bushels. But soon after, harvests started dropping. Around this time, hard clams first became an intensive topic of NYSG research and outreach. New York Sea Grant brought shellfish biologist Robert Malouf to New York on a Sea Grant professorship. During the 1980s, he, along with his colleagues and their many students, developed what Schlenk says “still stands as some of the best information we have about hard clam reproduction, predation, growth, and feeding.”

To support its focus on the hard clam resource and industry, NYSG also funded and coordinated a large set of studies of the Great South Bay in the early 1980s. These efforts culminated in, among other things, numerous journal articles and the production of the landmark The Great South Bay book. Landings continued to decline, however, and baymen gradually moved to other fisheries or left the water altogether.

While the 1980s suite of NYSG-funded clam-related studies gave the industry and managers much-needed knowledge, continued declines in growth rate and recurring brown tides made it clear that a re-examination was essential. “A general assumption was that the hard clam’s decline could be attributable to a number of factors, but some evidence suggested that the situation was changing further,” says Schlenk.

Thanks to then-Congressman Mike Forbes’ interest in the South Shore Estuary Reserve, in October 1999, NYSG announced that it would administer $427,500 in funds from the Northeast Regional office of the National Oceanic and Atmospheric Administration’s National Marine Fisheries Service (NMFS) for a new research initiative to investigate the population dynamics...
Lobster Mortalities and Shell Disease

In June 2001, the Long Island Sound Lobster Research Steering committee announced federal funding for 18 research projects that will improve what is known about the causes, extent, and persistence of conditions that led to die-offs and shell disease of the American lobster (Homarus americanus) in the Sound during 1999 and 2000. These research projects—most of which will start this summer and run two years—are jointly-funded under the $3.5 million Long Island Sound Lobster Initiative, an endeavor of Sea Grant programs in New York and Connecticut along with the Connecticut Department of Environmental Protection (CT DEP).

Research will address the health and disease of lobsters and the influence of environmental stressors, including temperature and toxic contaminants such as pesticides on lobster mortality and shell disease. “This effort promises to be an excellent example of federal-state collaboration,” says Mattice. “The initiative’s research projects should provide evidence to select among the many potential causes of the lobster mortalities and sickness.”

Federal monies for the Sea Grant projects (six each by the NY and CT programs) are funneled to the Sea Grant programs via National Marine Fisheries Service, which will conduct three projects of its own with the federal dollars. Connecticut Governor Rowland made $1 million in funding available for three additional CT DEP projects. CT DEP and NYS DEC each are receiving 1.3 million federal dollars for monitoring in LIS. Other collaborators include representatives of Long Island Sound lobster fishers’ organizations and the US Environmental Protection Agency.

Both the New York and Connecticut Sea Grant programs will use some of the lobster allocation to keep the lobster fishers, resource managers and the public informed about how the research is progressing. “Research is a dynamic and collaborative effort,” says NYSG lobster outreach specialist Antoinette Clemetson, “and the program’s success depends on the lobster fishing community’s willingness to cooperate with our scientists and vice-versa.” Clemetson’s role will be to keep the lines of communication open between the scientists and the stakeholders through a series of newsletter updates, workshops and other outreach techniques coordinated with Connecticut Sea Grant.

of hard clams in Long Island’s south shore estuary. “This targeted allocation of federal dollars for hard clam research could not have come at a better time,” says Schlenk. In December 1999, $50,000 was added to the initiative’s pot for research by the Port Authority of New York and New Jersey, which was also supporting a hard clam stock assessment on the New Jersey side of Raritan Bay (part of the lower New York Harbor). New York Sea Grant contributed an additional $100,000 and $50,000 is anticipated for the SSER.

Three research teams, two of which are led by investigators from outside New York, have recently begun two-year projects:

Roger Newell of the University of Maryland Horn Point Lab has teamed up with Southampton College’s Stephen Tettelbach in an effort to determine if reproductive cycles of adult hard clams in Long Island’s south shore bays are still synchronized to normal patterns of primary production. If conditions are shown not to be optimal, the use of hatchery seed clam production for re-stocking the bays may be advised as a short-to-medium-term-management strategy.

A research team at Stony Brook University—led by Robert Cerrato, Glen Lopez, Darcy Lonsdale, Roger Flood, Robert Armstrong and Jeffrey Levinton—will examine the trophic interaction between hard clams and phytoplankton. In effect, the team is testing the idea that the reduction in clam abundance may have propelled its population and associated ecosystem into a state where the scope for its growth has been reduced. Further, the clam’s steady declines in abundance in different habitats suggest one or more widespread or chronic causes.

Identifying the controlling factors related to hard clam growth, survival and environmental interactions will be the goal of the third and final research endeavor, to be headed by Eileen Hoffman of the Center for Coastal Physical Oceanography at Old Dominion University, Norfolk, Virginia. The multi-institutional team’s project summary states, “The primary objective of this effort is to develop a population growth model for the hard clam. This model will permit evaluation of the potential effects of changes in biological and environmental components of the Great South Bay system on the resident hard clam population levels and production.”

This enameled metal lobster sculpture, on display in Southampton this spring, was done by student Greg Lesiewicz, son of a long-time Long Island lobsterman.
LIS Lobster Initiative

“The research topics highlighted in our request for proposals are a direct result of the year 2000 meetings,” says NYSG Director Jack Mattice. In April 2000, over 250 lobstermen, researchers, state managers, legislators and environmental organizations came together for the first annual LIS Lobster Health Symposium in Stamford, Connecticut.

The gathering in Connecticut – which featured experts who discussed some of the then-current hypotheses to explain the lobster die-off in the Sound – was succeeded by May 2000’s “Lobsters and the Long Island Sound: 1999-2000.” This meeting, at Stony Brook University, gave researchers and administrators an opportunity to discuss with lobstermen the research priorities that came from April’s symposium.
